Final report

Approved for public release; distribution is unlimited

ABSTRACT: The U.S. Army Corps of Engineers (CE) is the largest federal provider of water-based recreation. It manages over 450 water resource development projects throughout the United States. These lake and river projects provide significant recreation opportunities and benefits to visitors and local residents, accommodating over 385 million person visits in 1999.

The purposes of this research are to develop visitor spending profiles and to estimate local and national economic effects of spending by visitors to CE projects. A visitor survey was conducted in the summer of 1999 through early 2000 at 16 CE projects across the nation. The survey was administered by the Engineer Research and Development Center of the U.S. Army Corps of Engineers and the Department of Park, Recreation and Tourism Resources at Michigan State University, with assistance from managers and staff at all 16 participating CE projects.

Segmented spending profiles were developed that can be tailored to project-level spending based on regional visitation data. Total recreation visitation was estimated by using information gathered from this study and from the Natural Resource Management System database. Economic effects of CE visitor spending were estimated by applying visitor spending and use data to regional economic multipliers generated from economic input-output models. These results provide a database for further analyses and improvements in future studies like these.

Preface

The work reported herein was conducted as a part of the Recreation Management Support Program (RMSP). The RMSP is sponsored by the Headquarters, U.S. Army Corps of Engineers (HQUSACE), and is assigned to the U.S. Army Engineer Research and Development Center (ERDC) under the purview of the Environmental Laboratory (EL). Funding was provided under Department of Army Appropriation No. 96X3123, Operation and Maintenance. The RMSP was managed by Ms. Judy Rice, HQUSACE.

This report was prepared by Drs. Wen-Huei Chang, Dennis B. Propst, and Daniel J. Stynes of the Department of Park, Recreation and Tourism Resources, Michigan State University, and Mr. R. Scott Jackson of the EL.

The study was supervised by Dr. Michael Passmore, Chief, Ecological Resources Branch, Ecosystem and Engineering Division (EED), EL. General supervision was provided by Dr. David J. Tazik, Chief, EED, and Dr. Elizabeth Fleming, Acting Director, EL. Technical reviewers were Ms. Kathleen Perales and Dr. H. Roger Hamilton, EL.

COL James R. Rowan, EN, was Commander and Executive Director of ERDC. Dr. James R. Houston was Director.

1 Introduction

The U.S. Army Corps of Engineers (CE) is the largest federal provider of water-based recreation. It manages over 450 water resource development projects (hereafter referred to as “projects”) throughout the United States. These lake and river projects provide significant recreation opportunities and benefits to visitors and local residents, accommodating over 385 million person visits in 1999 (“Natural Resource Management System (NRMS) 2000”). Spending by visitors on goods and services associated with the CE recreation program has an important influence on economic development in many regions of the United States and is an important component of the nation’s economy (Jackson et al. 1996).

The most recent nationwide study found that in 1996 about \$5.6 billion was spent by CE recreation visitors on trips within 30 miles (48 km) of all CE projects. This spending resulted in \$2 billion in income and over 120,000 jobs in industries directly providing goods and services to CE visitors. Secondary effects of CE visitor spending accounted for an additional \$1.3 billion in income and 53,000 jobs (Propst et al. 1998).

Economic effects of CE recreation visitor spending have also been estimated at regional and state levels. At the regional level, economic effects of visitor spending for 12 individual projects (Propst et al. 1995a-f; Stynes et al. 1995a-f) and the Upper Mississippi River System (Carlson et al. 1995) were estimated. State level economic effects stemming from both trip and durable goods expenditures were estimated by Jackson et al. (1996).

Reliable estimates of the regional effects of recreation require precise and current measures of money spent by visitors while engaged in recreation-related activities to CE projects. Visitor expenditures are typically arrayed as “spending profiles,” which are vectors of average amounts spent (for itemized goods and services) in conjunction with recreational visits to CE projects. Nationally representative visitor spending profiles were developed from survey data collected during 1989 and 1990 at a sample of 12 CE projects (Propst et al. 1992). The results of the 1989-90 survey indicate that spending patterns were highly variable across visitor segments. Significant differences in spending patterns were found to be associated with whether visitors stayed overnight during their visit, the type of lodging they used, boat usage, and whether visitors lived within or outside the county or counties in which the site was located. Results from the 1992 report provide information useful in developing effective sampling strategies for the survey employed in this study.

The purposes of this research are to update the Propst et al. (1992) spending profiles and to estimate local and national economic effects of spending by visitors to CE projects. Segmented spending profiles were developed that can be tailored to project-level spending based on regional visitation data. These spending profiles can then be used for economic impact analysis to estimate how visitor spending benefits regions surrounding CE projects.

To update the spending profiles, a sample of visitors from 16 CE projects reported the amounts they spent for goods and services during their trips to the projects. Spending averages were computed and multiplied by visitation statistics to estimate total annual visitor spending. Generalized spending profiles were developed for two sets of visitor segments: (1) campers, other overnight visitors, and day users, and (2) boaters and nonboaters. These profiles were applied to recreation use data gathered from this survey and from the NRMS to estimate total spending by each segment for each of the 456 CE projects. Sales, income, and employment effects within the local region surrounding each of the 456 CE projects were estimated by applying total visitor spending to regional economic multipliers. The national economic effects were estimated by applying total CE spending to the Micro-Implan Recreation Economic Impact (MI-REC) (Stynes, and Propst 1996; Chang and Propst 2000) and Impact Analysis for Planning (IMPLAN) (Minnesota IMPLAN Group, Inc. 1999) systems.

Note that the term “economic effects” rather than “economic impacts” is used in this study for the economic benefits associated with visitor spending. This is to distinguish two kinds of economic impact analyses identified in previous papers as “significance” and “impact” analysis (Stynes and Propst 1992):

- **Significance analysis** identifies the overall contribution of visitor spending to the region. How much of the sales, income, and employment in the area is associated with visitor spending? No attempt is made here to use a “with vs. without” framework. All spending of recreation visitors associated with their visits to the lakes, including spending by both local residents and tourists, can be included.
- **Impact analysis** identifies the changes in economic activity within the region that results from some action. The spending and related economic activity included in an impact analysis rest on a clear “with vs. without” framework. Only spending that would not otherwise have occurred in the region should be counted (Stynes et al. 2000).

Since the economic impact estimates in this report include the overall contribution of visitor spending from both residents and nonresidents (i.e., a significance analysis), the term “economic effects” is used to indicate that this is not a “pure” economic impact analysis where only effects from new money (i.e., nonresidents) are included.

The remaining report is divided into four sections. The methods section describes the sampling design and approaches used to measure recreation spending and economic effects. The results section reports visitation, spending profiles,

and economic effects for regions surrounding CE projects and the United States as a whole. The limitation section includes issues related to the data analysis and measurement approaches used in this study. The applications and recommendations section provides guidelines and options for applying these results, including local- (project-) level economic impact analysis. Suggestions for improving the credibility of spending profiles and economic impact analysis are also identified in this section.

2 Methods

Survey Site Selection

A total of 16 projects were selected for this study. The site selection procedures were as follows:

- a. All 456 CE projects were assigned to one of four groups based on a classification system developed by Becker (1997). In Becker's study, a total of 108 highly visited CE projects were grouped into three categories based on the number of retail establishments and population of the surrounding areas. Five other projects were later added bringing the total to 113 (see Appendix A). The remaining 343 projects were categorized as the fourth group. Projects of the first three groups accounted for 67 percent of CE's total visitation in 1996.
- b. Eight projects were randomly selected from each of the four groups with the possibility of selection proportional to visitation (32 projects were selected at this point).
- c. Project managers of the 32 projects were asked, in the order in which the projects were selected, to participate in this study. This process was repeated until four project managers in each group agreed to participate. The geographical locations of these 16 projects are shown in Figure 1.

Survey Procedures

Michigan State University (MSU) and the U.S. Army Engineer Research and Development Center (ERDC) developed survey instruments to be used in onsite and mailback surveys (Appendices B and C). Eight hundred surveys were distributed to each of the 16 selected projects across the country. Completed surveys were returned to MSU for processing and analysis. The purpose of the onsite survey was to collect general use data needed for profiling and segmenting of visitors. The purpose of the mailback questionnaire was to measure trip-related expenditures.

Staff at ERDC and MSU visited 4 of the 16 selected projects prior to the survey to provide training materials and observe potential problems. They met with the interviewers (project personnel) and answered questions that they had regarding survey procedures. A website containing survey instructions and

Figure 1. Locations of the 16 CE projects selected for study

frequently asked questions was also developed by MSU staff to assist project managers conducting the survey.

CE personnel distributed and collected the onsite questionnaires and distributed the mailback questionnaires to visitors. During the onsite survey, the CE staff would read the instructions and ask visitors to complete the questionnaire. After completing the questionnaire, those agreeing to complete the mailback portion would receive the survey from CE personnel. Written instructions were provided to the interviewers to follow in obtaining onsite visitor information and distributing mailback questionnaires. These guidelines addressed the allocation of surveys among visitor segments and the random distribution of questionnaires among recreation areas and time periods.

The timeframe for this survey was from June 25 through September 6, 1999, with a total of 24 weekend days and 50 weekdays.¹ A quota of 800 surveys was set for each project.² The 800 surveys were distributed among the three market segments according to the following quotas:

- 400 campers (surveyed at campsites).
- 200 boaters (surveyed at boat ramps to both day and overnight visitors).

¹ Except for Lake Okeechobee, which ran through January 2000.

² Except for Bonneville Lock and Dam. Only 200 surveys were distributed since no camping and boating facilities were available at this project.

- 200 other nonboating visitors (surveyed at other day use areas to both day and overnight visitors).

Two thirds of the questionnaires were to be distributed on weekend days and one third on weekdays. Survey quotas were also set for various recreation areas at each project in order to obtain the identified target sample for each of the three market segments. Quotas of surveys for individual recreation areas were proportional to reported visitation based on NRMS.

A primary purpose of this study was to obtain a sufficient sample of each segment in order to develop credible expenditure profiles. Since campers and boaters are in the minority at CE projects in comparison to day use nonboaters, these two large categories of visitors were purposefully oversampled out of proportion to their visitation shares. When aggregated visitor information was reported (i.e., party size for all visitors rather than just a given segment), the overall averages were weighted by the 1999 NRMS visitation data for each segment. This was done to convert the survey data into nationally representative information pertaining to CE recreation visitors.

A survey schedule for selected recreation areas at each project was developed. The quota was five visitors per day on a randomly selected weekday and ten visitors per day on a randomly selected weekend day for each market segment. For example, suppose recreation area A's schedule was:

Rec. Area A	Weekday	Weekend
Camper	6/30	6/27 8/15
Boater	7/13 7/19	7/25

In this case, 5 campers were to be sampled on June 30 (weekday), 10 campers on both June 27 and August 15 (weekend). Five boaters were to be sampled on both July 13 and July 19 and 10 boaters on July 25. In this example, the total number to be sampled for weekday campers was 5, weekend campers 20, weekday boaters 10, and weekend boaters 10.

Instructions were provided to interviewers on how and where to approach visitors in each of the three segments. Interviewers were asked to obtain the list of campers scheduled to depart on the sampled day from a given campground and randomly draw their samples from the list. CE personnel were informed of the importance of distributing the questionnaires on visitors' departure days to eliminate the sampling bias caused by the length of stay. In other words, by sampling only on departure days, researchers eliminated the situation where those who camped longer had a higher chance of being selected.

Instructions were also provided for sampling boaters and other nonboating visitors. In general, boaters and other nonboating visitors were surveyed when they were leaving the recreation areas. Boaters were to be surveyed after they pulled their boats out of the water at the boat ramp and were making preparations to depart. Other nonboating visitors were to be surveyed in the parking lot when they were preparing to leave. This was done so that every visitor party had an

equal chance of being sampled regardless of their length of stay in the recreation areas.

Survey Instruments

Visitor characteristics and trip information were gathered through the onsite surveys while trip spending was measured through the mailback surveys. The CE visitors interviewed onsite were asked questions regarding their current trips such as party size, expected length of stay, and primary purpose (Appendix B). The respondents were asked to report trip spending on the mailback questionnaires after they returned to their homes. Ten spending categories were provided on the mailback questionnaires for trip expenses on lodging, food, transportation, recreation, and other goods or services (Appendix C).

Data Cleaning and Editing

Several rules were set for data cleaning and editing. These rules were made to ensure consistency in data analysis and to filter out extreme numbers (outliers) that would have distorted the results. Reasons for data editing and elimination of cases are described in Appendix D.

Recreation Visits by Segment

Per person trip visits by segment were estimated using the information gathered from this survey and the 1999 Project Recreational Use (PR_USE) database and the 1998 Current Use Fee Area Information (CUR_FEE), Open Facilities (OPEN_FC), and Recreation Area (AR_MAIN) databases¹ from the NRMS. The total number of visitors, number of day users, and percentage of boaters were obtained from the PR_USE database, while the number of campers was estimated from the CUR_FEE, OPEN_FC, and AR_MAIN databases. The PR_USE database contains a project-level reporting of total visitation in person trips (visits) and the percentages of campers and boaters among all visitors. These percentages were based on surveys and therefore subject to sampling and other survey errors.² Not all projects have conducted surveys in recent years and therefore the estimates may be dated if visitation patterns have changed over time. CUR_FEE contains a site-by-site reporting of all the revenues and fees collected and the number of designated campsites where fees were charged. CUR_FEE was thought to be a more accurate measure of camping visitation than PR_USE because CUR_FEE is based on fees collected and is updated annually whereas PR_USE is based on traffic estimates applied to survey weights conducted in the past. The OPEN_FC database contains the number of all campsites regardless of whether fees were charged in each recreation area for both CE- and non-CE-managed sites. The AR_MAIN database contains information about the

¹ The latest available CUR_FEE database was 1998.

² Results from the CE Traffic-Stop Recreation Use Surveys reported in the Visitor Estimation and Reporting System were the main sources of these percentages.

managing agency for individual recreation areas. The OPEN_FC and AR_MAIN databases were used to estimate the number of campers who stayed at non-CE-managed campgrounds.

In order to estimate total number of campers at each project, total campground use fee revenues (CG_FEE_REV, a field within the 1998 CUR_FEE database) were divided by an average fee per night to estimate the number of camping nights. An average fee of \$8 per campsite per night was used taking into account fees at sites with and without electricity, fees at CE-managed and non-CE-managed facilities, and discounts for holders of Golden Age and Golden Access Passports. Camp nights at CE-managed sites were then expanded to include non-CE-managed sites by assuming similar occupancy rates at CE- and non-CE-managed sites. The estimated 1998 camper visitations were then projected to 1999 by using the ratios of 1999 to 1998 camper visits from the PR_USE database. The total CE camping visitation was 7.3 million party days estimated from the revenue data (Table 1), an increase of 1 million from the 1996 estimate (Propst et al. 1998).

Table 1
Summary of Recreation Visits to CE Projects, 1999¹

Visitation	Camper		Day User		Other Overnight ²		Total
	Boat	Nonboat	Boat	Nonboat	Boat	Nonboat	
Visits (person trips, MM)	1.2	4.3	80.8	288.1	2.4	8.6	385.5
Average Length of Stay (days)	4.2	3.8	-	-	2.4	3.0	-
Average Party Size (persons)	3.5	2.8	2.8	2.8	3.3	2.5	-
Visits (party days, MM)	1.4	5.9	29.0	104.1	1.8	10.5	152.8

¹ Sources: 1999 NRMS PR_USE database; 1998 NRMS CUR_FEE and PR_USE databases.
² Assumes that 3 percent of day users stayed overnight in lodging accommodations outside of project boundaries.

The number of campers in party nights (camp nights) was then converted to camper “visits” using an average camper length of stay of 4.2 nights and party size of 3.5 for boaters and 3.8 nights and 2.8 people for nonboaters gathered from this study. The formula for converting camper party nights to camper person trips is as follows:

$$\text{Person trips} = \text{Party nights} \times \text{Average Party Size} / \text{Average Length of Stay}$$

Camper party nights must be converted to person visits to be consistent with the units for which total and day use visitation are reported in the NRMS system (PR_USE database). A “visit” is defined as the entry of one person onto a CE project to engage in one or more recreational activities regardless of the length of stay. As used in this study, a “person trip” is equivalent to a “visit.” Total CE camping visitation nationally was 30.2 million visits (person trips) in 1999 based on the PR_USE database, whereas camping visitation derived from the CUR_FEE database was only 5.5 million person trip visits. The PR_USE

database estimate was more than five times the revenue-based estimate (Table 1).¹

The number of day use visits was derived by subtracting the revenue-based estimate of camper visits from total visits contained in the NRMS PR_USE database. Three percent of day users were set aside as other overnight visitors based on the survey results from this study. Visitors who stay in hotels, motels, vacation homes, friends and relatives, and other off-project lodging accommodations but visit the project for part of a day are treated as day users in the NRMS database. Since these “other overnight” visitors have significantly different spending patterns than typical day users (Propst et al. 1992), it is important to separate them from day users to estimate total spending. In the past, no information was available to estimate the percentage of day users staying overnight in the area. Following the assumption made in the 1994 study (Jackson et al. 1996), 1 percent of day users was set aside as other overnight visitors for the 1996 estimates (Propst et al. 1998). However, this percentage was adjusted upward to 3 percent in this study based on the new 1999/2000 survey information.

Campers, day users, and other overnight visitors were further divided into boaters and nonboaters based upon the proportion of boaters reported by each project in the 1999 NRMS database. This approach resulted in six visitor segments:

- Campers who boat.
- Campers who do not boat.
- Day users who boat.
- Day users who do not boat.
- Other overnight visitors who boat
- Other overnight visitors who do not boat.

Estimates of the number of visitors for each segment in person trips (visits) were converted to party days using average lengths of stay and party sizes for each segment (Table 1). The conversion to party days allows comparisons with previous studies (Propst et al. 1992, 1998).

Visitor spending was originally measured in party trips. To be compatible with NRMS data, all spending was converted to a per person trip basis. This conversion has the practical advantage of making the spending data more usable by project managers.

¹ The revenue-based estimate of camper visits in 1996 was 7.7 million. The reason for the difference (higher estimates in party days but lower in person trips when comparing the 1999 estimates to the 1996 estimates) was that different factors were used to convert camper party days to person trips. An average camper length of stay of 2.8 days and party size of 3.4 were used for the 1996 estimate. Because longer length of stay and smaller party size figures were used in this study compared to the 1996 study, the resulted estimates of camper person trips were smaller than the 1996 estimates.

Visitor Spending by Segment

Spending profiles for each of the six segments were developed. Trip spending included spending on goods and services consumed during a trip such as gasoline, food, and lodging in 10 spending categories. Expenditures for durable goods (items like boats and recreation vehicles that are used on multiple trips) were not included. Trip spending within 30 miles and outside 30 miles of the projects was estimated for each segment.

Due to the low response rates at some projects, the visitor segments were reduced to three (camper, day user, and other overnight visitor) when reporting spending profiles at the project level. The boater and nonboater segments were combined based on NRMS visitation shares so there would be a larger sample in each segment. The segmented visitor spending profiles (three segments) were estimated for three projects, Saylorville Lake, Barren River Lake, and John Martin Dam, where there were at least 10 surveyed visitors in each segment.

Estimates of Economic Effects

Four components are needed to estimate economic effects: recreation spending, visitor use estimates, capture rates, and economic multipliers (Jackson et al., 1992).

$$\begin{aligned}\text{Economic effects} &= \text{Number of visits} \times \text{Average spending per visit} \\ &\times \text{Capture rate} \times \text{Regional economic multiplier}\end{aligned}$$

For this report, the first two components were derived from the surveys and the NRMS database. Capture rates and economic multipliers were generated by the IMPLAN system. IMPLAN is a microcomputer-based input-output (I-O) modeling system that was originally developed by the U.S. Department of Agriculture, Forest Service, as a DOS application. It is currently maintained by the Minnesota IMPLAN Group Inc., which has modified IMPLAN to fit the Windows™ environment (Minnesota IMPLAN Group, Inc. 1999).

Local economic multipliers

Multipliers for regions around CE projects were estimated using regional models constructed with IMPLAN DOS version 91-F. These multipliers were estimated for a previous study that estimated local impacts of visitor spending at CE projects in 1996 (Propst et al. 1998; Becker 1997). Counties within a 30-mile radius of 108 projects were used as study regions (see Becker 1997 for details). An I-O model was estimated for each of these regions using the 1990 IMPLAN databases. Next, a national average recreation spending profile was applied to each model--with 100,000 visits as a consistent level of recreation use--and the various aggregate multipliers were then calculated from the impact analysis. These multipliers reflect the structural economic characteristics of each region. All the multipliers were price-adjusted to reflect the current year (1999). For

details on how local economic multipliers were estimated, refer to Propst et al. (1998).

The “average” project has a capture rate of 66 percent (Table 2), meaning that, on average, about two thirds of visitor spending in the local region was captured locally as direct sales effects. Direct effects are the changes in sales, income, and jobs in those businesses or agencies that initially receive the visitor spending (e.g., parks, motels, campgrounds, restaurants, grocery stores, attractions, and retail stores). Capture rates varied from 53 to 83 percent, with most projects ranging between 60 and 70 percent. The capture rate is not 100 percent due to an economic impact concept called “leakage.” In this case, “leakage” refers to visitor purchases of goods (e.g., gasoline, groceries and souvenirs) that are not manufactured in the local area. Only the retail margins associated with these purchases generally accrue to the local economy. The rest (wholesale, transportation, and manufacturing costs) escapes or “leaks from” the local area to distant intermediate or production sectors.

The Type I multiplier captures the indirect effects besides the direct effects from visitor spending.¹ Indirect effects are the changes in sales, income, and jobs in “backward linked” industries. These are firms that supply goods and services to those businesses that sell directly to the visitor. For example, motels purchase linen supplies, utilities, and other goods and services in the local area in order to provide lodging for the visitors. Indirect effects associated with recreation spending were quite small and exhibited limited regional variation. The average project had a Type I sales multiplier of 1.18, meaning that each dollar of direct sales generated an additional 18 cents in sales in industries that supply goods and services to tourism businesses (i.e., “backward linked” industries). The Type I sales multiplier varied minimally from 1.09 to 1.28 across the 108 projects.

The Type III multiplier captures both indirect and induced effects.² Induced effects are the changes in economic activity in the region resulting from household spending of income earned through the direct or indirect effects of the visitor spending. For example, motel and linen supply employees live in the region and spend some of their earnings on housing, groceries, education, clothing, and other goods and services. This spending will generate new rounds of sales, income, and job effects. The average project had a Type III sales multiplier of 1.66, meaning that each dollar of direct sales generated 18 cents in indirect sales and another 48 cents in induced effects. Type III sales multipliers varied somewhat more than their Type I counterparts from a low of 1.4 to a high of 2.0.

The Type III multipliers used in this and the previous reports were adjusted downward to correct for a bias in the IMPLAN DOS version multiplier procedures. The induced effects estimated in the DOS version of IMPLAN (version 91-F) assumed an average salary associated with each job. As wages in recreation and tourism-related sectors are lower than average, this approach recirculates too much income as induced effects. Therefore, induced effects were

¹ The Type I multiplier is the ratio of direct plus indirect effects to direct effects.

² The Type III multiplier is the ratio of direct plus indirect plus induced effects to direct effects.

recomputed based on total income generated rather than jobs.¹ For recreation spending, the revised induced effects are about half of those estimated with the standard IMPLAN Type III procedures. The adjusted multipliers are comparable to those from the newer Windows version of IMPLAN when the traditional Type II multipliers are used. However, researchers now recommend the use of the Type SAM multipliers generated by the latest version of IMPLAN-Pro as these most accurately reflect induced effects in outdoor recreation and tourism applications (Stynes et al. 2000).

The SAM framework tracks both market and nonmarket flows. The non-market flows are transactions between nonindustrial institutions such as households to government, government to households, and so on. These flows are called “inter-institutional transfers” (Alward and Lindall 1996). Since total personal income is income from all sources, including employment income and transfer payments that are based on both place of work and place of residence, some of this income may not be related to personal consumption expenditures in the region. The SAM multiplier approach enables the model to account for commuting, social security tax payments, household income tax payments, and savings and hence adjusts the Type II multipliers for income that is not normally spent immediately within the region, such as commuting workers who live outside the region and retirement benefits (Minnesota IMPLAN Group, Inc. 2000). The Type SAM multipliers are more conservative than the traditional Type II multipliers for tourism and recreation applications as the induced effects are smaller and are likely more realistic for tourism and recreation applications (Stynes et al. 2000). Researchers have found that Type SAM multipliers are still 10 to 20 percent lower than downwardly adjusted Type III multipliers. Thus, total economic effects in this report may still be inflated by 10 to 20 percent. Type SAM multipliers are not used in this report for project-level impact estimates because the authors wanted to be able to compare the economic effects in this report with comparable data in previous reports (e.g., Propst et al. 1998).

Income and job multipliers were used to convert direct sales to direct, indirect, and induced income and employment effects. Type I income multipliers measure the direct and indirect income associated with each dollar of direct sales, while Type III multipliers also measure the induced effects. For an average project, each dollar of direct sales generated 52 cents in direct income, 9 cents in indirect income (0.61 minus 0.52), and 16 cents in induced income (0.87 minus 0.61) in the local region (Table 2). Employment multipliers are defined similarly but on the basis of the number of jobs per million dollars in direct sales. For an average project, each million dollars in direct sales supported about 32 direct jobs, 3 indirect jobs (35 minus 32), and 8 induced jobs (43 minus 35) for a total job impact of 43 jobs per million dollars of direct sales (Table 2).

Total visitor spending was obtained by multiplying average spending per person trip by the number of person trips for each segment and then summing the results across segments. Economic effects at the project level were estimated by multiplying total visitor spending by capture rates and multipliers that were unique to each project (averages were used when there were no multipliers

¹ For details on the revised Type III multipliers, refer to Propst et al. (1998).

Table 2
Economic Multipliers for Regions Surrounding 108 CE Projects¹

Multiplier	Sales	Income ²	Jobs ³
Average Across 108 Regions			
Direct effects	1.00	0.52	31.86
Type I multiplier	1.18	0.61	34.48
Type III multiplier	1.66	0.87	42.81
Capture rate ⁴	0.66		
Range (minimum - maximum)			
Type I multiplier	1.09 - 1.28	0.51 - 0.72	21.78 - 49.57
Type III multiplier	1.37 - 1.99	0.66 - 1.11	27.74 - 59.43
Capture rate ⁴	0.53 - 0.83		

¹ Region defined as all counties within 30-mile radius of the project. Multipliers were originally computed by Becker (1997) using IMPLAN DOS version 91-F with 1990 database. All the Type III multipliers were modified downward to adjust the induced effects bias and price-adjusted to reflect current year value based on the approaches used in the 1996 regional impact report (Propst et al. 1998).

² Income per dollar of direct sales. Income includes employee compensation and proprietor and other property income.

³ Jobs per million dollars in direct sales. Jobs are not full-time equivalent. Any full-time and part-time job is counted as one job.

⁴ Capture rate is the percentage of visitor spending captured as direct sales within the region.

estimated for the projects). Only trip spending within 30 miles of the projects was included in local economic effect estimates.

National economic effects

National economic effects of CE visitor spending on trips were estimated by applying total trip spending (including both within and outside 30 miles of the projects) to an I-O model of the U.S. economy. A U.S. model was developed using IMPLAN-Pro version 2.0 with a 1997 database. Visitor spending was multiplied by total use to estimate total U.S. spending by CE visitors. The MI-REC system was used to bridge the total spending into the appropriate industrial sectors of the U.S. I-O model (Stynes and Propst 1996; Chang et al. 1998). Total employment, income, and sales due to direct and secondary effects were estimated by IMPLAN.

Two adjustments were made for the estimate of national economic effects. First, visitor spending outside 30 miles estimated for this study was adjusted upward based on the results of a previous study (Propst et al. 1992). This adjustment was necessary due to the low response rates and low sample sizes in certain segments. Total visitor spending outside 30 miles was adjusted upward from \$1,895 million to \$3,775 million. This adjustment was done by multiplying the Propst et al. (1992) results (price-adjusted to 1999) by the ratio of within 30-mile spending between the two surveys. This adjustment increased the estimated total visitor spending for both within and outside 30 miles from \$8,009 to \$9,888 million.

The national estimates of employment effects were adjusted based on the approach described in Stynes et al. (1998). The need for this adjustment stems from an issue of scale in which local jobs to sales ratios are much higher than the national ratios. Local regions around CE projects averaged 32 direct jobs per million dollars in direct sales, while the United States as a whole averaged 15 jobs per million. This adjustment is based on the facts that direct jobs are created primarily in the local areas around CE projects where the costs of labor are lower, making the ratio of jobs to sales higher.

National job effects estimated in this report were adjusted for this problem. The local models were assumed to yield an accurate estimate of the direct jobs associated with direct local sales to visitors. The revised national estimates of direct job effects were the sum of local direct jobs plus direct jobs from the sales that occurred outside the local areas. That is, the local jobs to sales ratios were applied to sales captured within local regions and the national ratios were applied to sales captured outside local regions. This same approach was also used to adjust the secondary job estimates and national job impact estimates for all trip spending.

3 Results

The results are provided in seven sections. The first section presents response rate data. The second section describes the characteristics of the respondents. Section three provides respondents' recreational use information and spending profiles across all projects. Visitors were grouped into six market segments based on their lodging types and boating activity. Section four reports recreational use information and spending profiles separately for three individual projects. Section five describes the economic effects of visitor spending at the project level, and sections six and seven summarize the economic effects of visitor spending at district, division, and national levels.

Response Rates

A total of 8,101 parties were approached for the onsite surveys. A party was defined as all occupants of a single vehicle. Of these parties, 47 refused to participate and 8,054 completed the onsite surveys. One hundred and twenty-four parties who completed the onsite surveys refused to participate in the mailback surveys, leaving a mailback sampling frame of 7,930 parties. Of the remaining 7,930 parties who agreed to participate in the mailback surveys, 1,650 returned their trip spending questionnaires, yielding a response rate of 21 percent (Table 3). The response rates ranged from 31 percent at Barren River Lake to 7 percent at Murray Lock and Dam.

Because names and addresses were not obtained during the onsite interviews, it was not possible to employ the usual follow-up reminder techniques that typically enhance response rates in sample surveys. Not having names and addresses also prevented checking for nonresponse bias (i.e., the extent to which the spending profiles of those who did not return their mailback questionnaires were different from those who did). The seriousness of the low response rate and its implications in terms of data usefulness are discussed in the limitations section of this report. For now, it is important to note that the sample sizes were sufficient to develop credible spending profiles for the six segments at the national level, which was one of the primary purposes of this study.

Response rates for the six targeted visitor segments are shown in Table 4. These response rates varied significantly from segment to segment. The other overnight/boater segment had the highest response rate at 29 percent, while the day user/nonboater segment had the lowest response rate at 11 percent. In

general, overnight visitors had higher response rates than day visitors, and boaters had higher response rates than nonboaters.

General Characteristics of CE Recreation Visitors

Visitor use and spending information were weighted by the 1999 NRMS visitation data of each segment as provided in Table 1. The general characteristics of CE recreation visitors are shown in Figures 2-7. Sixty-seven percent of the CE visitors lived within 30 miles of the CE projects (Figure 2). When asked

Figure 2. Permanent residence of CE visitors (weighted by the NRMS visitation data), 1999 (n = 7,790)

Figure 3. Primary purpose to visit the area where respondents were interviewed (weighted by the NRMS visitation data), 1999 (n = 7,782)

Figure 4. Percentage of CE visitors who stayed overnight within 30 miles of the projects (weighted by the NRMS visitation data), 1999 (n = 7,979)

Figure 5. Lodging type for CE visitors who stayed overnight within 30 miles of the projects (weighted by the NRMS visitation data), 1999 (n = 4,256)

Figure 6. Recreation activities participated in on current trip (weighted by the NRMS visitation data), 1999 (n = 7,840). Note: Camping was excluded from this estimate because it was treated as a type of lodging in the survey

Figure 7. Primary activity participated in on current trip (weighted by the NRMS visitation data), 1999 (n = 7,650)

about why they visited the area where they were surveyed, 56 percent reported that their primary purpose was to visit the given lake. Another 33 percent reported they visited the area because they lived nearby (Figure 3).

In total, only 4 percent of the visitors stayed overnight when visiting CE projects (Figure 4). About 33 percent of the visitors who stayed overnight stayed in campgrounds. Another 25 percent of the overnight visitors stayed in hotels or motels (Figure 5).

Picnicking and swimming were the most frequently participated activities for all CE visitors. About 37 percent of the visitors said they picnicked when they visited the CE projects and 35 percent said they swam (Figure 6). The participation rates for all other activities were between 10 and 20 percent. When asked to identify the primary activity on their trips to the lakes, almost 20 percent of the visitors reported swimming and 12 percent reported picnicking. About 22 percent of the visitors reported either fishing from boat or fishing from shore as their primary activities (Figure 7). Participation in outdoor recreation activities was highly seasonal. Since the surveys were not begun until June, it is not surprising that swimming and picnicking ranked this high. If the surveys had begun in April or earlier, it is likely that fishing may have received a higher ranking (this is particularly true for projects in the South).

Trip Spending and Other Characteristics

Typical CE visitors (i.e., the weighted average of spending profiles for the six segments) in 1999 spent \$15.47 per person trip within 30 miles of the project and \$4.80 outside 30 miles of the project for a total of \$20.26 for the entire trip (Table 5). Of the expenditures made within 30 miles of the project, visitors spent the most on groceries, restaurants, and gas and oil (about \$3 to \$4 per person trip on each category). Spending on these three categories accounted for about 70 percent of the total spending. The overall party size (weighted average) was 2.77 people and the length of stay within 30 miles of the project was slightly more than 1 day (0.14 nights) for all visitors.

On a segment-by-segment basis, the per person trip spending within 30 miles of the project varied from \$12 for day use nonboaters to \$84 for overnight boaters (Table 5). Total trip spending, both within and outside 30 miles, varied from \$15 per person trip for day use nonboaters to \$107 for overnight boaters. In general, boaters spent more than nonboaters, and overnight visitors and campers spent more than day visitors.

The percent errors (standard error divided by mean) for trip spending were about 5 percent for campers and 20 percent for the other overnight visitors. The percent errors for the day user segments (boaters or nonboaters) were about 10 percent. The 95-percent confidence interval for trip spending for each segment is average spending plus and minus two standard errors. Thus, the 95-percent confidence interval for spending within 30 miles of the project for campers who boated was \$58.50 to \$71.50 per person trip (\$65 plus or minus \$6.50). This

1 Pct. Error = Standard Error / Mean. Two standard errors equal 95% confidence interval.
 2 Weighted average of the six segments based on visitation in Table 1.

means that if the study were repeated 100 times, the average spending amount by this segment would fall between \$58.50 and \$71.50 in 95 out of 100 repetitions. This is a respectable error range for visitor expenditure surveys in general and is consistent with the 1989/90 survey results (Propst et al. 1992). The reason why the percent error, and hence the confidence interval, doubles and then quadruples from campers to day users to other overnight visitors, respectfully, is related to sample size. Since the formula for computing sampling error has sample size in the denominator, as sample size decreases, percent error increases. In examining the results in Table 5, sample sizes for the other overnight segments are relatively small and hence the relevant spending profiles are less stable and reliable (i.e., more prone to error) than those of the campers and day users.

Trip Spending and Other Characteristics at the Project Level

Only three projects had sufficient sample sizes to justify the computation of spending profiles from the survey data: Saylorville Lake, Barren River Lake, and John Martin Dam (Tables 6 - 8). Due to the low sample size at the project level, the visitor segments were reduced to three instead of six. The boater and non-boater segments were combined based on percent of boaters reported in the NRMS so there would be more sample in each segment. The three segments were then weighted based on visitation computed in Table 1 to compute the overall averages in the last columns of Tables 6-8. Among these three projects, the lowest weighted average spending for trips within 30 miles of the project was found at Barren River Lake (\$11 per person trip); the highest weighted average spending was at John Martin Dam (\$26 per person trip). Since day users accounted for more than 95 percent of the total visits at all three projects according to the NRMS data, the differences in weighted average spending at these projects were heavily influenced in a downward direction by the day user spending, which is typically much lower than that of campers and other overnight segments. The average spending for day users was \$10 at Barren River Lake, \$17 at Saylorville Lake, and \$25 at John Martin Dam for trips within 30 miles of the project.

The weighted average party size ranged from 2.45 people at John Martin Dam to 2.8 people at Barren River Lake. These numbers are similar to the 16-lake average of 2.77 people (Table 5). The numbers of nights away from home were also similar to the 16-lake average at two out of the three projects. Visitors spent an average of 0.12 nights and 0.14 nights within 30 miles of John Martin Dam and Barren River Lake, respectively, while the overall average for the 16 lakes was 0.14 nights. Visitors spent an average of 0.25 and 0.22 total nights away from home (within and outside 30 miles) on trips to John Martin Dam, respectively, while the overall average for the 16 lakes was 0.23 nights. The nights away from home were higher for Saylorville visitors. The average was 0.19 nights on trips within 30 miles and 0.3 nights in total trip length.

¹ Boaters and nonboaters were combined based on percent of visitors boating at each project (from 1999 NRMS database).

² Pct. Error = Standard Error / Mean. Two standard errors equal 95% confidence interval.

³ The 16-project average spending for the other overnight nonboater segment was used to compute weighted spending for the other overnight segment. This was done due to low sample size (less than 5) for the other overnight nonboater segment at this project.

⁴ Averages are weighted by the number of visits by each of the three segments at this project.

⁴ Averages are weighted by the number of visits by each of the three segments at this project.

Economic Effects at the Project Level

The project-level estimates of visits, spending, economic effects, and multipliers are reported in Appendix E. Visits were estimated for all 456 projects using the 1998 and 1999 NRMS project-specific data (Table E1). Estimates of economic effects for these projects were based on the spending profiles developed in this study and multipliers generated from 108 I-O models for the regions around each project (Table E5). The spending profiles (within 30 miles only) in Table 5 were applied to visitation at each project to obtain estimates of total spending (Table E2) and economic effects on sales (Table E2), income (Table E3), and jobs (Table E4).

Barren River Lake (in Louisville District) serves to illustrate the interpretation of the findings, as well as the approach. Barren River Lake reported 1.5 million visits in 1999 with camping revenues of \$205,608 (1998 figures). There were 365 CE-managed campsites at Barren River Lake and 99 non-CE-managed campsites. Boaters accounted for 13 percent of the visits. Based on these data from the 1999 and 1998 NRMS databases, Barren River Lake hosted 26,000 camping visits (person trips), 1.45 million day use visits, and 43,000 other overnight visits (Table 9). Based on the camping revenue data used in this report, 1.7 percent of visits to Barren River Lake were by campers, as opposed to the 10-percent figure from the PR_USE database in the NRMS. By multiplying visitor spending for each segment by total number of visits for each segment, total spending for each segment was estimated. In total, recreation visitors to Barren River Lake spent \$22.49 million in the local area in 1999 (Table 9).

Table 9
Visitation and Spending at Barren River Lake, 1999

Table 10
Economic Effects of Visitor Spending at Barren River Lake, 1999

Effect	Direct	Indirect	Induced	Total
Sales (\$MM)	14.75	2.66	7.03	24.44
Income (\$MM)	7.65	1.39	3.87	12.90
Jobs ¹	470	39	123	632

¹ Not full-time equivalent. Any full-time and part-time job is counted as one job.

Barren River Lake is illustrative of projects where primary spending data were collected (Table 7) and project-specific multipliers were estimated for the surrounding region using an I-O model. The multipliers for Barren River Lake are reported in Appendix Table E5. Sixty-four percent of the \$22.49 million in visitor spending was captured as direct sales by the local economy -- \$14.75 million in sales (Table 10). These direct sales

accounted for another \$2.66 million in indirect sales and \$7.03 million in induced sales for a total sales effect of \$24.44 million.

Income and employment effects for Barren River Lake are interpreted similarly. Visitor spending accounted for \$7.65 million in income and 470 jobs in businesses directly serving visitors (Table 10). Another \$1.39 million in income and 39 jobs were associated with backward-linked industries through indirect effects. Total effects including direct, indirect, and induced effects of the \$22.49 million visitor in spending were \$24.44 million in sales, \$12.90 million in income, and 632 jobs in the local region.

Economic Effects at District and Division Levels

The availability of visitation, spending, and economic impact estimates for all 456 CE projects makes it a simple task to generate economic effects for CE districts and divisions. Division and district totals are reported in Table 11. It should be noted that these are simply aggregations of the local impacts of individual projects in each district or division. The findings do not therefore cover all impacts on the larger region, but only the sum of the impacts on local areas around projects in a given district or division. A complete estimate of impacts for the larger regions would need to include visitor spending outside local areas surrounding each project and should employ multipliers for the larger region. However, to estimate multipliers at district and division levels is beyond the scope of this project and requires additional data that were not available for this study.

Approximately half of the income and employment effects occurred in two of the Corps' eight divisions: Great Lakes and Ohio River, and Southwestern. Fifty-five percent of these effects occurred in seven of the Corps' 31 districts. Comparisons of the relative impacts of projects in each district or division should take into account the demographic and economic characteristics of the regions. For example, a thousand jobs in a district with relatively low population and economic activity has a much greater relative impact than a thousand jobs in a heavily populated, economically diverse district. District and division personnel may find these comparisons useful, especially when compared with the economic effects of other industries (e.g., agriculture or manufacturing). However, since the estimates at district and division levels do not cover all impacts on the larger region (i.e., they are only the sum of the impacts on local areas around projects), recreation impacts may be underestimated when compared with other industries' impacts at the district and division level.

National Economic Effects

Aggregation of local effects

The aggregation may be taken one step further to the national level, with the same caveats as above. Summing visitor spending at all 456 projects (Table E2) yielded a total of \$6 billion in trip-related expenditures associated with recreational use of CE projects in 1999 (Table 12). These were trip expenditures

Table 11

¹ From Table 1.
² Total Spending = Average spending per person trip (from Table 5) × Visits in person trips.

within 30 miles of CE projects and not total trip expenses. Day users accounted for 84 percent of this total spending. Other overnight visitors accounted for 11 percent of total spending as compared to 5 percent for campers. Boaters accounted for 22 percent of visits on CE projects and 31 percent of all spending.

In 1999, the \$6 billion in visitor spending associated with the CE recreation program resulted in direct effects of approximately \$3.9 billion in sales, \$2 billion in income, and 123,000 jobs within the counties around CE projects (Table 13). When secondary effects were considered, the local economic effects of CE visitor spending totaled \$6.5 billion in sales, \$3.4 billion in income, and 166,000 jobs. It is important to recall that these effects were the result of spending by CE visitors locally (within 30 miles of projects' borders) and employed local area multipliers, not national ones. Total effects represented slightly more than 0.1 percent of total U.S. jobs and 0.05 percent of total U.S. income. In terms of secondary impacts, induced effects dominated indirect effects by about 3 to 1. This reflects the labor-intensive nature of the tourism industry.

Table 13 Economic Effects of Recreation Visitor Local Trip Spending on 456 CE Projects,¹ 1999			
Effect	Sales (\$MM)	Income (\$MM)	Jobs (number of jobs) ²
Direct	3,912	2,024	123,380
Indirect	706	369	10,217
Induced	1,864	1,022	32,762
Total Effects	6,481	3,416	166,358

1. Impacts on counties within 30 miles of CE projects of visitor trip spending within 30 miles of the projects. The total trip spending was \$5,962 million.
2. Includes full-time and part-time jobs.

Use of national I-O model

The economic effects of CE visitor spending on the U.S. economy were also determined by applying total spending to a U.S. I-O model. Total trip spending for all CE visitors in the United States was estimated by applying average person

trip spending to the total number of person trips for each segment in Table 1. Trip spending for the entire trip (both within and outside 30 miles) was used to estimate the economic effects of CE visitors' trip spending on the U.S. economy. The estimated trip spending for all CE visitors in the United States in 1999 was \$7.8 billion from the survey. For reasons previously explained in Chapter 2, this figure was adjusted upward to \$9.6 billion.

Ninety-two percent of CE visitor spending was captured by the national economy, 8 percent went to foreign imports, which resulted in a direct sales effect of \$8.9 billion (Table 14). This spending also resulted in \$3.9 billion in direct income and supported about 200,000 direct jobs. When secondary effects were considered, the national economic effects of CE visitor spending totaled \$10.6 billion in income and about 350,000 jobs. Total effects from total trip spending represented slightly more than 0.2 percent of total U.S. jobs and 0.15 percent of total U.S. income. It is important to distinguish these results (U.S. model, or "top-down" approach) from the aggregation of local effects (local models, or "bottom-up" approach). The top-down effects were the results of total trip spending by CE visitors (both within and outside 30 miles of projects' borders) and employed national multipliers. These effects were much higher than the aggregation of local effects because of the higher capture rate (most of the spending was captured by the U.S. economy) and higher multipliers.

Table 14
Economic Effects of CE Visitor Total Trip Spending on the U.S. Economy,¹ 1999

Effect	Sales (\$MM)	Income (\$MM)	Jobs (number of jobs) ²
Direct	8,909	3,866	199,192
Indirect	6,662	3,197	60,458
Induced	6,673	3,548	87,201
Total Effects	22,244	10,610	346,851

¹ Impacts of total trip spending both within and outside 30 miles of the projects. Because of low response rates and low sample sizes on some segments, the total trip spending was modified upward from the survey estimate of \$7,810 million to \$9,644 million. This modification was done by comparing visitor spending outside 30 miles estimated from this study to the 1989/1990 survey (Propst et al. 1992).

² Includes full-time and part-time jobs.

4 Limitations

The major limitation of this study is the uncertainty about representativeness of the sample due to the low response rates to the mailback portion of the survey. The low response rates resulted from a combination of factors: the inability to send follow-up reminders and the use of project personnel to make visitor contacts and distribute the survey instruments. Sending two follow-up reminders, as typically recommended in survey research, normally doubles the response rate in visitor expenditure surveys (Dillman 1978), but increases the cost and requires visitors to provide their names and addresses. Even though project personnel were trained and the research personnel at MSU were available to answer questions, it is not possible to know the extent to which procedures and instructions were followed. Even under the best of circumstances, visitors may respond differently to government employees distributing questionnaires than to trained interviewers who are under government contract.

Having noted this important limitation, we still feel that eight of the twelve national spending profiles in Table 5 are representative and reliable enough to be used to estimate economic effects and for other purposes. We say this with some confidence because we were fortunate to have the results of a similar study conducted 10 years earlier. In this study (Propst et al. 1992), a similar methodology was followed with two major exceptions: two follow-up reminders were sent and a small number of trained, university graduate student researchers distributed the surveys. In the earlier study, the response rates were 60 to 80 percent, much higher than in the current study. By price-adjusting and then comparing the results of this study with those of Propst et al. (1992), Chang and Propst (2000) were able to conclude that there were no significant differences between the spending profiles for the camper and the day user segments (boaters and nonboaters, both within 30 miles, and for total trip spending) between the two studies. This provides a good deal of confidence in using the figures from the 1999 survey for these segments and referring to the data as "nationally representative." The same cannot be said about the other overnight segments, for which there were fairly major differences between the two studies. For this reason, we recommend using the price-adjusted profiles from Propst et al. (1992) rather than from this study for the four other overnight segments.

A second limitation was related to the timing of the beginning of the survey. The availability of funding for the study necessitated beginning the surveys in June. However, half of the sampled projects were located in the southern tier of states where the recreation season, particularly as related to fishing, begins much earlier (February - April). This is the time during which fishing tournaments are

typically held. According to project managers, these fishing tournaments attract anglers who spend a great deal of money in the local area. Thus, it is not clear how much our spending figures for the camping, day use, and other overnight segments were affected by not surveying this category of visitor more completely. Since the NRMS reports annual, not seasonal, visitation, the use estimates should be inclusive of the early season anglers and other visitor types. To check the accuracy of the spending profiles, the results from this study may be compared to the 1996 National Survey and Fishing, Hunting, and Wildlife-Related Recreation (U.S. Department of the Interior 1997), which is funded by the Fish and Wildlife Service of the U.S. Department of the Interior and Bureau of the Census of the U.S. Department of Commerce. Among other things, this survey reports angler expenditure data by state.

The third limitation is the use of the old IMPLAN Type III multipliers. The Type III multipliers used in this and the previous reports were adjusted downward to correct for a bias in the IMPLAN DOS version multiplier procedures. However, even with the adjustment, we found that the downwardly adjusted Type III multipliers are still 10 to 20 percent higher than the Type SAM multipliers. Type SAM multipliers are calculated by the latest version of IMPLAN-Pro and are thought to be more accurate in reflecting induced effects in outdoor recreation and tourism applications (Stynes et al. 2000). We did not use Type SAM multipliers in this report for project-level impact estimates because we wanted to be able to compare the economic effects in this report with comparable data in previous reports (e.g., Propst et al. 1998).

5 Applications and Recommendations

The economic effects estimated in this report may be used to assess the CE recreation program at the project, district, or division level. There are two basic applications, discussed below, that can be handled by utilizing the findings in this report.

Estimating Economic Effects of CE Visitor Spending in a Given Year

In this report, the economic effects of CE visitor spending in 1999 were estimated for each project, district, division, and the nation as a whole. CE managers may compute economic effects for any given year by using the following equation:

$$\begin{aligned}\text{Economic Effects} = & \text{Average Spending per Visit} \times \text{Total Annual Visits} \\ & \times \text{Capture Rate} \times \text{Regional Economic Multipliers}\end{aligned}$$

Managers should obtain updated NRMS visitation data (no conversion necessary since the spending data reported is in person trips), price inflate the spending data to the year of study, and apply the total spending to local capture rates and regional multipliers (assume capture rates and multipliers will not change too much over time). For a simplified approach on conducting economic impact analysis for CE projects, refer to the worksheet provided in Appendix A of Propst et al. (1998). For the range of multipliers and to download an Excel spreadsheet for the computation of economic impacts at multicounty level, visit the web page of Dr. Daniel Stynes, MSU, at <http://www.msu.edu/user/stynes/usace> (“CE Project Recreation Economic Impact Calculator”). Managers can also refer to the classification table (Appendix A) developed by Becker (1997) to choose multipliers by matching similar projects where multipliers have been computed.

Evaluating the Economic Impacts of a Proposed Action or Management Alternative

Evaluation of alternatives is another important feature of economic impact analysis. In this case, managers must define the action or alternative to be

evaluated and estimate the change in visitors and spending due to the action. For example, project managers and planners may conduct “what if” analysis by using the segmented spending profiles and regional multipliers reported in this study. Questions like “what if the percent of day use boaters increases from 20 to 40 percent at this project?” or “what if a new hotel is open on the lake (more overnight users)?” can be answered by applying the segmented spending profiles to the proposed change in visits.

This study interviewed about 8,000 visitors at 16 CE recreation project across the nation to collect recreation use information. More than 1,600 mailback questionnaires were returned from these visitors, and the results were used to estimate visitor trip spending. Total CE recreation visitation was estimated by using information gathered from this study and from the NRMS database. Economic multipliers were computed for the nation by using an I-O model, and the project-level multipliers were modified from a previous study. Economic effects of CE visitor spending were estimated by applying visitor spending and use data to regional economic multipliers. The analysis and findings in this report suggest a number of ways to improve future studies of this kind:

- a. Future studies like these should employ follow-up reminders (at least two) and use trained interviewers rather than project staff to distribute the surveys and instruct visitors. In comparing this survey with the survey conducted in 1989, it was concluded that the low response rate of this study was largely due to the lack of follow-ups. By employing follow-up reminders, the response rate may more than double and thus provide adequate sample sizes for individual projects and all visitor segments (resident and nonresident). Also, the use of trained interviewers instead of CE staff to distribute questionnaires will provide more control in survey quality since continuity among projects and surveys will result from trained staff with only one job.
- b. Future recreation use surveys could be modified to include variables useful for economic impact analysis. Information such as percent of residents vs. nonresidents, conversion variables for switching between different units (party trips to person days, etc.), and percent of CE visitors who stay overnight off premise can be gathered via other use surveys that the CE may conduct regularly or irregularly. With this information, the visitation estimates from the NRMS can be fine-tuned to better fit any future economic impact analysis.
- c. Newer IMPLAN databases should be obtained for updating regional economic multipliers. Currently, all the regional economic multipliers at the project level were estimated using the 1990 database. Although the errors due to multipliers are more likely to be the smallest compared to other components in an economic impact analysis (i.e., spending, visits, etc.), it will be very difficult to verify if the multipliers are still suitable for the region after more than 10 years. Also, the old database cannot be used in the current IMPLAN model (IMPLAN-Pro 2.0, Windows version) and thus cannot be used to compute the Type SAM multipliers. It is not necessary to obtain new IMPLAN databases and compute multipliers every year since multipliers typically do not change much over time (3 to 5 years). However, new databases should be obtained at least

every 5 years so the change in regional economies (i.e., new industries, shift in business types and linkages, population change) can be reflected in the multipliers.

 Note: All Type III multipliers were modified downward to adjust the induced effects bias (Propst et al. 1998).

Appendix B

Onsite Survey Questionnaire

U.S. ARMY CORPS OF ENGINEERS RECREATION VISITOR SURVEY

1. Including yourself, how many persons are in your vehicle today? _____
2. How many miles (one-way) did you travel from your home to this lake? _____
3. What is your primary purpose to visit this area? (check one)

1. [] Business trip	3. [] Stay at second home	5. [] I live in this area
2. [] Visit friends/relatives	4. [] Visit this Lake	6. [] Other (please specify): _____

4. Have you spent or do you plan to spend any nights away from your home while on this trip?

YES

NO →

4.e. How many hours will you spend in total at this lake today? _____

Proceed to question 4.a

Proceed to question 5.

4.a. How many nights will you spend away from your home on this trip? _____

4.b. How many of these nights will you spend within 30 miles of the lake? _____

4.c. What type of lodging are you using in the local area?
(check one)

- | | |
|--|--------------------------------------|
| <input type="checkbox"/> Campground | <input type="checkbox"/> Rental home |
| <input type="checkbox"/> Hotel/motel/lodge/cabin | <input type="checkbox"/> Boat |
| <input type="checkbox"/> Home of friends/family | <input type="checkbox"/> Second home |

4.d. Is this lodging: (check one)

- | | |
|---|--|
| <input type="checkbox"/> ON Corps' property | <input type="checkbox"/> OFF Corps' property |
|---|--|

5. What recreation activities have the people in your vehicle participated in, or plan to participate in, while on this trip to the lake? (check all that apply)

- | | | |
|---------------------------|------------------------------|--------------------------------------|
| 1. [] Fishing from boat | 4. [] Picnicking | 7. [] No particular activity |
| 2. [] Fishing from shore | 5. [] Swimming | 8. [] Other (please specify): _____ |
| 3. [] Other boating | 6. [] Hiking/walking/biking | |

6. What is your primary recreation activity on this trip to the lake? _____

7. What is the ZIP code of your permanent home? _____

Please return this questionnaire to your CE manager/staff. Thank you for your participation and have a nice day!

FILLED OUT BY CE MANAGER/STAFF ONLY

ID #: _____

Record time distributed _____ AM/PM

Appendix C

Mailback Survey Questionnaire

U.S. ARMY CORPS OF ENGINEERS RECREATION EXPENDITURE SURVEY**INSTRUCTIONS**

Please fill in the blanks below for spending on your party's recent trip to the CE Lake. The amounts in COLUMN A and B should add up to the total amount of money your party spent for that item.

EXAMPLE

Let's say the people in your vehicle spent \$52 at hotels within 30 miles of the lake and spent zero on lodging anywhere else. You would enter \$52 in COLUMN A and "0" in COLUMN B for this item. In addition, your group spent \$60 at restaurants during the trip, of which \$22 was spent within 30 miles of the lake, you would enter \$22 in COLUMN A and \$38 in COLUMN B for this item.

	<u>within 30 miles</u> (Column A)	<u>beyond 30 miles</u> (Column B)	Please enter 0 if you spent nothing: DONT LEAVE BLANKS!
1. Hotels, motels, cabins, B&B, rental homes	\$ <u>52</u>	\$ <u>0</u>	
2. Restaurants, bars, and other eating and drinking places	\$ <u>22</u>	\$ <u>38</u>	

The questions that follow are based on
your recent recreation trip to the:

ID # : <ID> - _____

«PROJ NAME»
Project

Where you were interviewed on _____ / _____.

Recreation Area Name

At that time there were _____ people in your vehicle.
Record expenses for these people only.

START HERE

	<u>Spending within 30 miles of the lake</u> (Column A)	<u>Spending beyond 30 miles</u> (Column B)
--	--	--

LODGING

1. Hotels, motels, cabins, B&B, rental homes	\$ _____	\$ _____
2. Campground fees (including hookups)	\$ _____	\$ _____

FOOD AND BEVERAGES

1. Restaurants, bars, and other eating and drinking places	\$ _____	\$ _____
2. Groceries, and take out food including alcohol and tobacco	\$ _____	\$ _____

TRANSPORTATION

1. Gas and oil for auto, boat, RV, etc.	\$ _____	\$ _____
2. Other auto expenses (repairs, parking, tolls, etc.)	\$ _____	\$ _____
3. Other boat expenses (repairs, rentals, slip fees, etc., <i>excluding equipment</i>)	\$ _____	\$ _____

RECREATION

1. Attractions, entertainment, and recreation fees (including day use fees at Corps of Engineers day use areas)	\$ _____	\$ _____
2. Sporting goods and boat equipment	\$ _____	\$ _____

OTHER EXPENSES (clothing, souvenirs, maps, books, etc.)	\$ _____	\$ _____
--	----------	----------

After recording your expenses, please answer these two questions.

1. In total, how many nights did you spend away from home on this trip? _____ nights
2. How many nights did you spend within 30 miles of the lake where you were interviewed? _____ nights

You can peel off this yellow sticker and seal this form (optional) before you drop it into a mailbox.
No need to add postage. THANK YOU FOR YOUR HELP

Appendix D

Data Editing and Cleaning

Data Editing and Cleaning

Rules and variable definitions:

1. Resident: based on miles traveled from home. 0-29 miles = resident; 30 and more miles = nonresident.
2. Overnight users: visitors who spent nights away from home.
3. Camper: respondents who answered camping as the type of lodging in question 4, or mentioned camping in question 5 or 6 in the onsite survey were coded as campers.
4. Other overnight visitors: visitors spent over night other than campers.
5. Party size: based on onsite survey. If no data available from the onsite survey, information from the mailback survey was used.
6. Nights away from home: based on mailback surveys. If no data available from the onsite survey, information from the mailback survey was used.
7. Boater: respondents who checked boating in question 5, or mentioned any boating activities in question 5 or 6 in the onsite survey were coded as boaters.

Re-coded cases:

1. Anyone who spent money on boating categories was coded as a boater.
2. Overnight visitors who only spent money on camping but did not spend money on other types of lodging were re-coded as campers.
3. Overnight visitors who spent money on *both camping and other lodging types* were examined and coded on a case-by-case basis.
4. Overnight visitors who returned mailback surveys but were unable to be matched with onsite surveys (i.e., no ID numbers on the mailbacks) were coded as campers if they spent money on camping; otherwise coded as other overnight users.
5. The spending on lodging was zeroed out if the respondent was identified as day user.

Filtered cases:

Fifty-seven cases were eliminated from final analysis due to one or both of the following situations:

1. Visitors who stayed for more than 30 days were excluded from the analysis since they would have an upward bias to the average per trip spending.
2. Cases were excluded when the reported party sizes were more than 12 people. This was done to eliminate the group tours that would distort the average per party spending.

Detection of outliers:

1. Survey responses were examined on a case-by-case basis for any single entry of spending that was more than \$500 for any item. The corresponding per-day and per-person expenses were reviewed so large spending figures were not categorized as outliers simply because the visitors stayed longer in the region.
2. Ten spending entries were identified as outliers: one reported \$500 on hotel expense for one night for a party of two; two others reported more than \$60 per night of camping fees at Corps campgrounds for groups of two and three people; three visitors reported \$3,100 on groceries for 1 day (company picnic expenses); four visitors reported spending more than \$2,000 on sporting goods (\$2,000, \$15,000, \$33,000, and \$35,000).

Appendix E

Summary Results for all Corps of Engineers Projects

(Sheet 1 of 15)

¹ Impacts on counties within 30 miles of CE projects of visitor trip spending within 30 miles of the projects.

Notes: LRD = Great Lakes and Ohio River; MVD = Mississippi Valley; NAD = North Atlantic; NWID = Northwestern; POD = Pacific Ocean; SAD = South Atlantic; SPD = South Pacific; SWD = Southwestern.

! Projects where surveys were conducted to create the spending profiles for this study.
Projects where the IMPLAN economic impact models have been built (Becker 1997).

(Sheet 1 of 15)

Impacts on counties within 30 miles of the projects. Income includes employee compensation and proprietor and other property income.

Notes: LRD = Great Lakes and Ohio River; MVD = Mississippi Valley; NWD = Northwestern; POD = Pacific Ocean; SAD = South Atlantic; SPD = South Pacific; SWD = Southwestern.

¹: Projects where surveys were conducted to create the spending profiles for this study.

#: Projects where the IMPLAN economic impact models have been built (Becker 1997).

(Sheet 1 of 14)

Impacts on counties within 30 miles of CE projects of visitor trip spending within 30 miles of the projects. Includes full-time and part-time jobs.

Notes: LRD = Great Lakes and Ohio River; MVD = Mississippi Valley; NAD = North Atlantic; NWD = Northwestern; POD = Pacific Ocean; SAD = South Pacific; SWD = Southwestern.

1. Projects where surveys were conducted to create the spending profiles for this study.

#. Projects where the IMPLAN economic impact models have been built (Becker 1997).

(Sheet 1 of 4)

Region defined as all counties within 30-mile radius of the project. Multipliers were originally computed by Becker (1997) using MPPLAN DOS version 91-F with 1990 database. All Type III multipliers were modified downward to adjust the induced effects bias and price-adjusted to reflect current year value based on the approaches used in the 1996 regional impact report (Propst et al. 1998).

² Capture rate is the percentage of visitor spending captured as direct sales within the region.

³ Income per dollar of direct sales. Income includes employee compensation and proprietor and other property income.

⁴ Jobs per million dollars in direct sales. Includes full-time and part-time jobs.

Notes: LRD = Great Lakes and Ohio River; MVD = Mississippi Valley; NWD = North Atlantic; NWD = Northwestern; POD = Pacific Ocean; SAD = South Atlantic; SPD = South Pacific; SWD = Southwestern.

13. SUPPLEMENTARY NOTES					
14. ABSTRACT <p>The U.S. Army Corps of Engineers (CE) is the largest federal provider of water-based recreation. It manages over 450 water resource development projects throughout the United States. These lake and river projects provide significant recreation opportunities and benefits to visitors and local residents, accommodating over 385 million person visits in 1999.</p> <p>The purposes of this research are to develop visitor spending profiles and to estimate local and national economic effects of spending by visitors to CE projects. A visitor survey was conducted in the summer of 1999 through early 2000 at 16 CE projects across the nation. The survey was administered by the Engineer Research and Development Center of the U.S. Army Corps of Engineers and the Department of Park, Recreation and Tourism Resources at Michigan State University, with assistance from managers and staff at all 16 participating CE projects.</p> <p>Segmented spending profiles were developed that can be tailored to project-level spending based on regional visitation data. Total recreation visitation was estimated by using information gathered from this study and from the Natural Resource Management System database. Economic effects of CE visitor spending were estimated by applying visitor spending and use data to regional economic multipliers generated from economic input-output models. These results provide a database for further analyses and improvements in future studies like these.</p>
